Abstract. – OBJECTIVE: This review aims to determine whether there is considerable evidence that mouthwashes containing chlorhexidine (CHX) lower the COVID-19 virus load in saliva.

MATERIALS AND METHODS: A comprehensive literature search was carried out in PubMed/Medline, EMBASE, LILACS, Scopus, Web of Science and Cochrane Library, Google Scholar, Open Gray, and ProQuest electronic databases using the keywords: “coronavirus infections” or “coronavirus” or “covid 2019” or “sars 2” or “sars-cov-2” or “sars-cov-19” or “severe acute respiratory syndrome coronavirus 2” or “coronavirus infection” or “severe acute respiratory pneumonia outbreak” and “CHX” or “CHX Hydrochloride” or “CHX Digluconate.” A manual search of the articles was also conducted utilizing the reference lists of articles. The in vitro experimental and clinical studies that tested CHX mouthwash were included. Study selection was not restricted or limited to a specific gender, age, ethnicity of individuals, or time of publication. A mix of keywords and proper truncations were used to search for databases.

RESULTS: Twelve studies (7 clinical and 5 in vitro) published between 2020 and 2021 were included in this systemic review. Five randomized controlled trials and one clinical case series demonstrated the effectiveness of CHX in reducing the oral viral load; one was inconclusive. Of the five in vitro studies, three showed that CHX is effective against SARS-CoV-2, and two studies denied the effectiveness of CHX. All in vitro studies tested CHX activity concentrations of 0.2, 0.12, and 0.1%. One study reported more than a 99.9% reduction in SARS-CoV-2 viral load in a minimal contact time of 30 seconds. CHX exhibited potent antiviral activity at higher concentrations without cytotoxicity.

CONCLUSIONS: Despite differences in the published research, CHX at different concentrations may be effective in lowering the SARS-CoV-2 viral load in saliva.

Key Words: CHX, Chlorhexidine, Mouthwash, COVID-19, Viral load, Effectiveness, SARS-CoV-2.

Introduction

Coronavirus Disease (COVID-19) affected almost all aspects of human life regardless of the established protocols to minimize its spread worldwide. COVID-19 is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV) that disseminated several years ago and was contagious to a lesser degree than COVID-19. SARS-CoV, belongs to β family of coronaviruses that can infect humans. COVID-19 infection includes oral manifestations, mainly taste disorders, oral mucosal lesions, and dry mouth. These manifestations are reduced after a negative polymerase chain reaction (PCR) test. However, other presentations include masticatory muscle pain, tongue, halitosis, and swelling.

The COVID-19 infection occurs through exposure to coughing, sneezing, or close contact with infected persons. The literature reports a viral load of up to 1.2x10⁸ copies/mL of COVID-19 virus in the saliva of symptomatic and asymptomatic carriers. Hence saliva plays an essential role in the transmission of the illness through the distribution of virus-infected droplets. Healthcare professionals, particularly dentists, are at extreme risk of exposure to pathogenic microorganisms, including COVID-19 infection. Accordingly, special attention has been given to dental practice due to the proximity of dentists to patients during dental procedures. Use of ultrasonic scalers, low-speed and high-speed handpiec-
es leads to the production and release of aerosols and droplets\(^{8,10}\). Droplets and aerosols that generate in the presence of the COVID-19 virus in the saliva of the infected patients could infect dental staff\(^{11,12}\). In addition, during the COVID-19 crisis, many dental clinics closed temporarily or permanently due to the failure to provide a virus-free environment regardless of the number of dental emergencies that needed urgent treatment\(^{13}\).

Few studies\(^{14-16}\) have reported salivary viral load reduction in aerosols production following dental procedures. The usage of effective mouthwash has been suggested to reduce oral viral load before dental treatment\(^{14}\). In addition, preprocedural mouthwashes are widely accepted because of their well-known effectiveness in reducing microbial load\(^{8}\). One of these mouthwashes is CHX, which is reported\(^{16}\) to be effective against respiratory viruses, but its efficacy against COVID-19 has not been proven. Therefore, due to the paucity of data in the literature, this systematic review aims to determine whether there is considerable evidence that mouthwashes containing CHX lower the SARS-CoV-2 virus load in saliva.

### Materials and Methods

The Preferred Reporting Items for Systematic Reviews and Meta-Analysis Checklist (PRISMA)\(^{17}\) was used to select studies (Figure 1). In addition, the PICO (population/patient/problem, intervention, control/comparator, and outcomes) approach was considered for framing a “foreground” research question\(^{18}\), as mentioned below.

\(P = \) Patient (subjects infected with coronavirus or the contaminated saliva of these individuals), \(I = \) Intervention (CHX Mouthwash), \(C = \) comparison (compared to a control group through a cross-sectional evaluation or compared to the same individual/saliva at first through a longitudinal assessment), \(O = \) outcomes (viral load or % of virus inactivation) and \(S = \) study design (clinical trials or \textit{in vitro} experimental studies).

### Inclusion Criteria

The \textit{in vitro} experimental and clinical trials that hypothesized CHX reduces viral load in saliva and used CHX mouthwash as an intervention were included in this review. The study was not restricted or limited to a specific sex, age, and race of individuals or the time of publication. However, only the articles published in English were considered for the review.

### Exclusion Criteria

The exclusion criteria were applied as follows: a) studies that did not test or used coronavirus-infected individuals/saliva as a sample, b) experiments that used samples other than saliva, c) articles that used other than CHX for decreasing the viral load (as an intervention) or that have used the mouthwash plus another treatment without separating their results, d) studies that lack a viral load evaluation after the intervention or have incomplete data, and e) conference proceedings, expert views, and letters.

### Information Sources and Search Strategy

For all the selected electronic databases, a combination of terms and suitable truncations were adapted to search literature in electronic databases of PubMed/Medline, EMBASE, Latin American and Caribbean Literature in Health Sciences (LILACS), Scopus, Web of Science and Cochrane Library. A combination of MeSH keywords was used until June 4, 2021. The search string used for the literature search in this study is shown below:

\(TI= (\text{"coronavirus infections" or "coronavirus" or "coviid 2019" or "sars2" or "sars-cov-2" or "sars-cov-19" or "severe acute respiratory syndrome coronaviruus 2" or "coronavirus infection" or "severe acute respiratory pneumonia outbreak" or "novel cov" or "2019ncov" or "sars cov2" or "cov2" or "ncov" or "covid-19" or "covid19" or "coronaviridae" or "corona virus" or "covid-19 pandemic" or "2019 novel coronavirus disease" or "sars-cov-2 infection" or "covid-19 virus disease" or "2019 novel coronavirus infection" or "2019-ncov infection" or "coronavirus disease 2019" or "coronavirus disease-19" or "2019-ncov disease" or "covid-19 virus infection" or "2019-ncov" or "sars-cov-2" or "sars-cov") and TI=("CHX" or "CHX Hydrochloride" or "CHX Gluconate" or "CHX Acetate"). In addition, Google Scholar, Open Gray, ProQuest were utilized to explore the gray literature. Finally, a manual search of the articles was also conducted using the bibliography of retrieved publications.

### Study Selection

The study selection was carried out through two stages. In the first stage, three individual reviewers screened the titles and abstracts of all studies independently. Studies that did not match the inclusion criteria were excluded. In the second stage, the same three reviewers reviewed the completed articles they agreed upon in the first stage. Any disagreements about a study and the opinion of the fourth reviewer were considered to finalize the decision.
Risk of Bias Assessment

In this review, the risk of bias for clinical studies was carried out using the Newcastle-Ottawa Quality Assessment Scale of the selected articles. The assessment was based on the selection of the samples, whether representative or not, presence or absence of the control group to ascertain that both the control and experimental groups had the same method and exposure (Table I).

Since there is no standard tool for the in vitro studies assessment, risk of bias analysis was done using the previous study approach, which was based on the quality of the report, performance, selection, and detection of bias. The assessment was done using 13 items labeled “low risk,” “high risk,” and “unclear” (Table II).

Data Collection

The data consisted of the study’s characteristics such as title, author name, country, study type, objectives, participants, controls, sample size, concentration of CHX, and main findings. Three reviewers collected the data independently in separate excel sheets. All three data sheets were carefully reviewed, discussed, and combined into one final sheet (Table III).

Statistical Analysis

It was determined that the clinical trials and in vitro studies outcomes could not be combined. The individual studies’ findings and features are shown in Table III using the qualitative analysis approach. Based on the type of research design,

all 12 papers included in this systematic review were classified as clinical trials or in vitro investigations. A total of 7 (58%) clinical trials and 5 (48%) in vitro investigations were reviewed further for quality criteria, and the key results were summarized and tabulated. Since this review did not include quantitative analysis of data from the studies, the statistical significance of the p-value cannot be computed.

Results

Study Selection
A total of 1,145 articles were identified from the various electronic databases. Subsequently, 1,129 references were duplicated and excluded from the study. Hence a total of 16 full-text articles were assessed for eligibility, and finally 12 studies were included in the systematic review after removing four studies for various reasons.

Characteristics of the Study
All 12 studies were published between 2020 and 2021. Seven were clinical studies, and the others were in vitro studies. Five randomized controlled trials\(^\text{20,23-26}\) and one clinical case-series\(^\text{21}\) involving two COVID-19 patients demonstrated that CHX is an effective preprocedural mouthwash in reducing the oral viral load. However, one randomized controlled trial was inconclusive on the effectiveness of CHX in decreasing the viral load in COVID-19 patients\(^\text{22}\). Of the five in vitro studies\(^\text{29-33}\), three of them\(^\text{29,30,33}\) showed that the CHX is effective against SARS-CoV-2. Contrarily, two studies\(^\text{31,32}\) did not report the effectiveness of CHX against the SARS-CoV-2.

Risk of Bias
The quality assessment of in vitro studies was carried out using the previous study’s approach\(^\text{29,30,31-33}\) as mentioned in the methodology. Most domains have been labeled as “low risk” (reporting quality and selection bias). “Unclear risk” rate was also high, and it was scattered along the domains; however, “high risk” was marked in three different studies reported by Jain et al\(^\text{29}\), Davies et al\(^\text{31}\), and Komine et al\(^\text{32}\) with regards to the scoring of the cell vitality and absence of industry sponsors.

Discussion
Current literature indicates that COVID-19 is easily transmitted by infected saliva through direct contact with the mucosa of the eye, nose, and mouth or indirectly by coughing or sneezing by an infected individual\(^\text{34,35,9}\). It is essential to reinforce the infection control protocols due to the virus’s high survival rates on hands and surfaces that come into contact with infected saliva. Disinfection of the dental clinic environment and personal protective equipment is essential to avoid the risk of cross-infection between patients and the dentist\(^\text{31}\). Some studies\(^\text{21,26}\) reported that the CHX provides an efficacious means of reducing the viral load. Nevertheless, using preprocedural CHX as a prevention strategy to decrease the risk of contagion may control the spread of COVID-19\(^\text{20,23,30}\).

All in vitro studies included in this article tested CHX activity against SARS-CoV-2 at concentrations of 0.2, 0.12, and 0.1%. Two studies\(^\text{31,32}\) reported that CHX has no antiviral activity with a less than 50% viral reduction. However, Jain et al\(^\text{29}\) found that the CHX reduced over 99.9% of the SARS-CoV-2 viral load with 30 seconds of contact time. In addition, Xu et al\(^\text{33}\) claimed that CHX has a medium antiviral activity with 50% viral load reduction when used at 0.12% concentration. However, it exhibits a potent antiviral activity at higher concentrations without cytotoxicity.

Decreasing the microorganism count in the mouth using commercially available chemical rinses preoperatively in controlling dental plaque is well-known\(^\text{36}\). Some studies\(^\text{37,38}\) claim that preventing the transmission of viruses and bacteria can be best managed using mouthwashes. Among these chemical agents, some have bactericidal efficiency, while others have virucidal efficiency. Current studies\(^\text{28}\) indicate using hydrogen peroxide, CHX, and PVP-I as a method or intervention to lessen the possibility of contamination. On the other hand, undesirable side effects of some agents may occur. Additionally, governments worldwide recommended methods for cleaning the environment to prevent the spread of the virus using hydrogen peroxide\(^\text{39,40}\). As reported in the literature, hydrogen peroxide is widely used as a surgical and oral disinfectant for treating gingivitis\(^\text{41,42}\).

Despite guidelines for diagnosing and treating new coronavirus pneumonia, the CHX is ineffective against SARS-CoV-2\(^\text{39}\). In this systematic review, we evaluated twelve studies, including seven in vivo and five in vitro. After assessing the studies with various parameters (CHX concentration, contact times, control), most articles supported CHX mouthwash as having a good antiviral effect against SARS-COV-2. One study\(^\text{33}\)
claimed that CHX could exhibit a potent antiviral effect at higher concentrations without cytotoxicity, giving CHX a great advantage. On the other hand, two studies\textsuperscript{31,32} have denied CHX as having an antiviral effect against SARS-COV-2. Despite CHX has an important function in dentistry and antisepsis, it may induce adverse consequences, limiting its usefulness\textsuperscript{43}. However, currently there is little information on how preprocedural mouthwashes diminish SARS-CoV-2 in saliva\textsuperscript{44}. Due to the lack of clinical studies with high sample sizes and consistent methodologies, it may be argued that there is insufficient data regarding the effectiveness of CHX in reducing the SARS-CoV-2 virus load. Hence further studies are recommended on this issue.

Conclusions

Based on \textit{in vitro} and clinical investigations, the findings of this review indicate that the use of CHX in different concentrations is likely effective in lowering the SARS-CoV-2 viral load in saliva. However, the degree of scientific evidence associated with CHX is highly frail owing to the absence of a large number of randomized clinical studies and the inclusion of \textit{in vitro} studies.
